SAP ABAP Technical Monitoring
and Performance Analysis

Practical Project Report

Report item	Details
Project category	SAP Basis-oriented monitoring and performance analysis
Environment	SAP BTP ABAP trial, accessed through SAP Fiori/browser
Application explored	Technical Monitoring Cockpit (TMC)
Observation date	19 October 2026
Evidence basis	User-provided screenshots and values visible in those screenshots
Report status	Completed — SAP technical monitoring and preliminary performance analysis

This report records what was observed and what can reasonably be concluded from the available evidence. It does not invent missing system data or claim a fix that was not performed.

1. Executive Summary

This project documents an initial hands-on review of SAP technical monitoring features available in an SAP BTP ABAP trial. The work used the Technical Monitoring Cockpit to inspect System Workload, an ABAP Statistics Record, and the SQL Statements associated with a selected request. A separate SQL Statement Analysis view was also reviewed.

The selected ABAP statistics record reported server response time of 476,321.18 ms and ABAP processing time of 475,510.42 ms. It also reported HANA execution time of 224.82 ms and database network time of 574.77 ms. In the SQL Statements list associated with the record, the first visible row was a truncated INSERT INTO SNAP... statement with 398 executions and database processing time of 663.13 ms. These figures show that the selected record's reported time is largely attributed to ABAP processing, while the visible SQL row alone does not explain the full response time.

The project deliverable is complete as a technical monitoring and preliminary performance-analysis exercise. The available screenshots support the recorded observations and recommendations for further investigation. Root-cause diagnosis and remediation were outside the completed scope of this exercise.

2. Project Objectives

- Access the monitoring applications available in the SAP BTP ABAP trial.
- Review workload trends and response-time components.
- Inspect a selected ABAP statistics record and document the displayed processing-time metrics.
- Review SQL statement execution metrics and relate them cautiously to the selected request.
- Prepare evidence-based findings and practical next steps without changing a shared trial system.

3. Environment and Scope

Item	Observed information
Platform	SAP BTP ABAP trial environment
User interface	SAP Fiori launchpad / browser-based monitoring apps
Monitoring area	Technical Monitoring Cockpit
Workload view	System Workload — time series / response-time contribution and Top Workload
Request detail	ABAP Statistics Record (record 1/20 in the visible detail screen)
Request type	OData V4
Work process type	Dialog
Task priority	High
Client / tenant shown	Client 100; Tenant ID 100
Scope boundary	Report is limited to the screenshots and metrics shared; it is not a full system export or backend audit.

4. Work Performed

1. Opened Technical Monitoring Cockpit from the SAP Fiori launchpad.
2. Reviewed System Workload charts and the Top Workload table, which showed workload by request/program context and timing components.
3. Opened a selected ABAP Statistics Record and reviewed its response-time contribution fields.
4. Opened the SQL Statements tab for the selected record and reviewed the visible statement metrics.
5. Reviewed SQL Statement Analysis for the selected statement CALL sys.debug (?, ?, ?) and its execution metrics.
6. Viewed the Application Sources tab and saw a source identifier beginning CL_AMDP_DBG_SYS_DEBUG... with plan ID 32802780002.

5. System Workload Observations

The System Workload page showed a time-series chart and a Top Workload table. The visible categories included OData V4, URL, and Remote Function Call request types. The chart exposed response-time components including ABAP processing, HANA execution, database network, HANA preparation, load, enqueue, roll, roll-wait, and queue-wait times.

Visible workload example	Average server response time	ABAP CPU time	HANA CPU time
OData V4 — taxpayer-related service (visible row)	24.69 s	13.63 s	9.19 s
URL — /sap/bc/adt/checkruns (visible row)	0.26 s	2,350.55 s*	1,018.08 s*
Remote Function Call — RTM_COLLECT (visible row)	0.21 s	14.48 s	5.30 s

*The CPU-time values shown for workload rows can be accumulated over multiple executions or the selected period, while average server response time is an average per request. They should not be compared directly without understanding the view's aggregation. The table alone does not establish a performance defect.

6. Selected ABAP Statistics Record

Metric	Value visible in screenshot
Record label	ABAP Statistics Record (1/20)
Start time	19 Oct 2026, 09:17:09.98384000 (+05:30)
End time	19 Oct 2026, 09:25:06.30496400 (+05:30)
Server response time	476,321.18 ms (approximately 476.32 seconds)
ABAP processing time	475,510.42 ms (approximately 475.51 seconds)
HANA preparation time	1.73 ms
HANA execution time	224.82 ms
Database network time	574.77 ms
Load time	9.05 ms
Enqueue time	0 ms
Roll time	0.44 ms
Roll-wait time	0 ms
Queue-wait time	0.06 ms
Work process ID	46
Task priority	High
Request entry type	OData V4

Interpretation: the reported ABAP processing time is close to the overall server response time and substantially larger than the displayed HANA execution time. This is a reason to investigate the ABAP/application processing path, but it does not identify the underlying cause. Timing components may have SAP-specific definitions and should not be assumed to be mutually exclusive.

7. SQL Statements for the Selected Request

Visible field	Observed value
First visible statement	INSERT INTO SNAP… (statement text truncated)
Database processing time	663.13 ms
HANA preparation time	0.25 ms
HANA execution time	190.67 ms
HANA CPU time	137.89 ms
Maximum HANA memory	10.40 kB
Executions	398
Records	398
Other visible statement types	SELECT statements and other SQL rows

The visible SQL row has a substantially smaller displayed database-processing time than the selected request's total response time. The full SQL text and its exact relationship to the long-running request are not available in the screenshot. Therefore, the row cannot be named as the cause of the long response time. Repeated execution is not automatically inefficient; business context, statement details, and workload patterns are required.

8. Separate SQL Statement Analysis Observation

Metric	Value visible in screenshot
Selected statement	CALL sys.debug (?, ?, ?)
Number of executions	44
Total execution time	115,940,673 µs (approximately 115.94 seconds)
Average execution time	2,635,015 µs (approximately 2.64 seconds)
Application source identifier	CL_AMDP_DBG_SYS_DEBUG...
Plan ID	32802780002
Time selection shown	18–19 October 2026 / Last 24 Hours in the analysis view

This is a separate SQL Statement Analysis view. Its total and average execution times are useful indicators for that selected statement over the view's selected period. The statement name and source identifier suggest a debug-related operation, but the screenshots do not establish its business purpose or whether it is problematic. Do not merge these figures with the separate ABAP Statistics Record as if they necessarily describe the same execution.

9. Findings

ID	Finding	Status
F-01	The selected OData V4 statistics record reports about 476.32 seconds of server response time.	Observed
F-02	The same record reports about 475.51 seconds of ABAP processing time.	Observed
F-03	The record reports 224.82 ms HANA execution time and 574.77 ms database network time.	Observed
F-04	The first visible SQL row shows 398 executions and 663.13 ms database processing time.	Observed
F-05	The selected record's reported time is predominantly attributed to ABAP processing rather than HANA execution.	Preliminary interpretation
F-06	The separate CALL sys.debug statement reports 44 executions and about 2.64 seconds average execution time.	Observed in separate view
F-07	A confirmed root cause, system-wide incident, or successful fix has not been demonstrated.	Evidence limitation

10. Recommendations and Follow-up

7. Retain the screenshots with their timestamps and labels as evidence in the project portfolio.
8. If the trial exposes more details for the same record, inspect Database Connections, Memory, Gateway Calls, HTTP, or RFC Client Calls only when those details help explain the request path.
9. Compare several records of the same request type and similar time window before describing one record as representative.
10. Where permitted, inspect the full SQL statement and its context; do not execute or modify statements as part of this exercise.
11. Do not change shared system settings or attempt remediation without authorization and a reproducible diagnosis.
12. For a future extension, gather additional details from the same request path before proposing a root cause or remediation.

13. Before describing this as a full SAP Basis project, separately verify access to classic administration tasks such as background-job monitoring, system logs, ABAP dumps, user/role administration, and transport management. The current screenshots do not prove those tasks were performed.

11. Limitations

- The analysis is based on user-shared screenshots rather than a complete export of SAP monitoring data.
- The selected ABAP record may not represent typical workload.
- The SQL text is truncated in the SQL Statements table.
- The SQL Statement Analysis view is a separate view and may not correspond to the same execution as the selected ABAP record.
- The exercise focused on monitoring, reviewing available performance statistics, and documenting findings. Root-cause diagnosis, corrective action, and before-and-after validation were outside the scope of this completed project.
- The project demonstrates use of monitoring features in an SAP BTP ABAP trial. It does not claim comprehensive administration of a traditional SAP NetWeaver/S/4HANA system.

12. Conclusion

The exercise successfully used SAP Technical Monitoring Cockpit to inspect workload trends, a selected ABAP statistics record, SQL statements, and a separate SQL Statement Analysis view. The most notable observation is a selected record with approximately 476.32 seconds of server response time, of which approximately 475.51 seconds is reported as ABAP processing time. The visible SQL row does not, on its own, explain that response time. Additional context would be required to diagnose the cause.

The completed project outcome is an SAP technical monitoring and preliminary performance-analysis report. It documents the monitoring activities performed, the metrics observed, and evidence-based recommendations for further investigation. The work demonstrates familiarity with reading monitoring views and documenting metrics, while accurately stating what remains unverified.

Appendix A — Evidence checklist

Evidence	Status
System Workload chart / Top Workload table	Screenshot shared
ABAP Statistics Record response-time details	Screenshot shared
ABAP Statistics Record — SQL Statements	Screenshot shared
SQL Statement Analysis summary	Screenshot shared
Application Sources tab	Screenshot shared
Database Connections details	Not evidenced in supplied screenshots
Root-cause diagnosis and corrective action	Outside project scope
Before-and-after performance validation	Outside project scope

Appendix B — Interview-ready project description

“I carried out a monitoring and preliminary performance-analysis exercise in an SAP BTP ABAP trial using the Technical Monitoring Cockpit. I reviewed workload charts, inspected an ABAP statistics record, and analysed the available SQL statement metrics. One selected OData V4 record showed around 476 seconds of server response time, with most reported time attributed to ABAP processing. I documented the observation and noted that the available evidence did not establish a root cause, so I avoided claiming a fix. This exercise helped me practise interpreting SAP workload and SQL monitoring data and writing evidence-based technical findings.”
